

# Structuring an eZ project

Since release 2015.10, eZ Platform is very close to the [standard Symfony distribution](#). It comes with default settings that will let you get started in a few minutes.

## The AppBundle

Most projects can use the provided `AppBundle`, in the `src` folder. It is enabled by default. The project's PHP code (controllers, event listeners, etc.) can be placed there.

Reusable libraries should be packaged so that they can easily be managed using Composer.

## Templates

Project templates should go into `app/Resources/views`.

They can then be referenced in code without any prefix, for example `app/Resources/views/content/full.html.twig` can be referenced in twig templates or PHP as `content/full.html.twig`.

## Assets

Project assets should go into the `web` folder, and can be referenced as relative to the root, for example `web/js/script.js` can be referenced as `js/script.js` from templates.

## Configuration

Configuration may go into `app/config`. However, services definitions from `AppBundle` should go into `src/AppBundle/Resources/config`.

## Versioning a project

The recommended method is to version the whole ezplatform repository. Per installation configuration should use `parameters.yml`.
